

# Solution Code

```
import java.io.*;
import java.util.*;
public class EmirpNumber
{
    public static boolean isPrime(int n)
    {
        if (n <= 1)
            return false;
        //loop executes from 2 to n-1
        for (int i = 2; i < n; i++)
            if (n % i == 0)
                //returns false if the condition returns true
                return false;
            //returns true if the condition returns false
            return true;
    }

    public static boolean isEmirp(int n)
    {
        if (isPrime(n) == false)
            return false;
        int reverse = 0;

        while (n != 0)
        {
            reverse = reverse * 10 + n % 10;
            n = n / 10;
        }
        if (isPrime(reverse) == false)
            return false;
        else
            return true;
    }
}
```

# Solution Code

```
//finds the last digit of the number (n)
int digit = n % 10;

//finds the reverse of the given number
reverse = reverse * 10 + digit;

//removes the last digit
n = n/10;

}

//calling the user-defined function that checks the reverse number is prime
or not

return isPrime(reverse);

}

//driver code

public static void main(String args[])
{
    Scanner sc=new Scanner(System.in);

    System.out.print("Enter a number to check: ");

    //reading an integer from the user
    int n=sc.nextInt();

    if (isEmirp(n) == true)

        System.out.println("Yes, the given number is an emirp number.");

    else

        System.out.println("No, the given number is not an emirp number.");
}
```
